

Climate Change Health Assessment - Alternative Assessment

This report presents an alternative assessment of climate-related health risks.

According to this assessment, climate change is not expected to cause a substantial increase in heat-related health problems in the near term. It states that current evidence does not establish a significant increase in heat-related illness by 2030.

The assessment also states that evidence linking climate change to changes in infectious disease patterns remains uncertain and varies substantially by region.

The report recommends that additional regional evidence should be collected before making strong conclusions about future health impacts.

The assessment emphasizes uncertainty in projections and states that health impacts can differ substantially between regions and populations.
